Neuter Operation Dog

Neutoring of a male dog is a surgical procedure performed under general anesthesia, during which the testicles are removed. It is a morning admission procedure. Once your dog has fully recovered from the anesthesia, you will be contacted to pick him up."

Preparation:

- Make sure your dog has been well walked before the surgery.
- Bring your dog on an ***empty stomach***: no food after 10:00 PM the evening before the procedure and no food on the morning of the surgery; drinking ***water*** is allowed.
- We recommend purchasing a recovery suit and/or a recovery collar (cone) to protect the wound. These can also be purchased through us.

Aftercare:

- Your dog has received an injection to prevent vomiting. If he is hungry, he may eat, but give small amounts to avoid nausea.
- On the day of the operation, your dog may still be drowsy and tired. We expect to see improvement the following day.
- Keep your dog calm: take only short walks for at least ***5 days***, and keep him on a leash for at least ***10 days.*** Do not allow him to swim.
- Keep the recovery suit and/or cone on for at least ***10 days,*** and check the wound daily.
- A free follow-up check is included after the operation. You can schedule this at the reception desk.

Contact us if:

- Your dog does not want to eat or drink the day after the procedure.
- Your dog becomes more lethargic on the day of the procedure.
- The wound becomes red, swollen, or starts to bleed.

Points of attention after castration:

After the procedure, your dog will have lower energy requirements. We recommend carefully monitoring the amount of food and your dog's weight. If needed, you may switch to a special diet formulated for castrated dogs.
